Problems Relating to Capital Structure and Leverage

1. EBIT and Leverage

Money Inc., has no debt outstanding and a total market value of $150,000. Earnings before interest and taxes [EBIT] are projected to be $14,000 if economic conditions are normal. If there is a strong expansion in the economy, then EBIT will be 30% higher. If there is a recession, then EBIT will be 60% lower. Money is considering a $60,000 debt issue with a 5% interest rate. The proceeds will be used to repurchase shares of stock. There are currently 2,500 shares outstanding. Ignore taxes for this problem.

a. Calculate earnings per share [EPS] under each of the three economic scenarios before any debt is issued. Also calculate the % changes in EPS when the economy expands or enters a recession.

If you ignore taxes in this problem and there is no debt outstanding:

Under Normal Economic Conditions

\[
\text{EPS} = \frac{\text{EBIT}}{\text{shares outstanding}} = \frac{14,000}{2,500} = 5.60
\]

Under Expansionary Times:

\[
\text{EPS} = \frac{[\text{EBIT} \times 1.60]}{\text{shares outstanding}} = \frac{14,000(1.3)}{2,500} = \frac{18,200}{2,500} = 7.28
\]

Under a Recession:

\[
\text{EPS} = \frac{[\text{EBIT} \times (1-.60)]}{\text{shares outstanding}} = \frac{14,000(.40)}{2,500} = \frac{5,600}{2,500} = 2.24
\]

% Δ EPS going from Normal ➔ Expansion:

\[
\frac{(7.28 - 5.60)}{5.60} = 0.30 \text{ or } 30\%
\]

% Δ EPS going from Normal ➔ Recession:

\[
\frac{(2.24 - 5.60)}{5.60} = -0.60 \text{ or } -60\%
\]
b. Repeat part (a) assuming that Money goes through with recapitalization. 
   What do you observe?
If the market value of the firm is $150,000 with 2,500 shares outstanding, then
the value of one share of stock is: $150,000/2,500 = $60/share.

If $60,000 worth of debt is raised to retire stock, then you will be buying back
$60,000/$60 or 1,000 shares. So, after recapitalization there will be 2,500
-1,000 or 1,500 shares outstanding.

EBIT will be reduced by the amount of the interest on $60,000 in debt or
$60,000 x .05 = $3,000.

<table>
<thead>
<tr>
<th></th>
<th>Recession</th>
<th>Normal</th>
<th>Expansion</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBIT</td>
<td>$5,600</td>
<td>$14,000</td>
<td>$18,200</td>
</tr>
<tr>
<td>Less: Interest</td>
<td>3,000</td>
<td>3,000</td>
<td>3,000</td>
</tr>
<tr>
<td>EBT=N1</td>
<td>$2,600</td>
<td>$11,000</td>
<td>$15,200</td>
</tr>
<tr>
<td>EPS</td>
<td>$1.73</td>
<td>$7.33</td>
<td>$10.13</td>
</tr>
</tbody>
</table>

Normal Conditions:
EPS = $11,000/1,500 = $7.33
Expansionary Times:
EPS = $15,200/1,500 = $10.13

% Δ EPS going from Normal ➔ Expansion:

\[
\frac{($10.13 - $7.33)}{$7.33} = .38199 \text{ or } 38.2\%
\]

Normal Conditions:
EPS = $11,000/1,500 = $7.33
Recession:
EPS = $2,600/1,500 = $1.73

% Δ EPS going from Normal ➔ Recession:

\[
\frac{($1.73 - $7.33)}{$1.73} = -.76398 \text{ or } -76.40\%
\]

The use of debt to buy back shares will cause a dramatic increase in EPS should the
economy stay normal or move to an expansionary state. On the other hand, if the
economy goes into a recession the leverage will cause EPS to decline by a much
greater % than the increase due to expansion. The firm would also need to consider
the market price of its stock [whether it is on sale], the prospects for earnings even in
the event of a recession [i.e., does the firm produce a product or service that everyone
needs [somewhat inelastic good/service]], and whether the financing rate is attractive
[spread between the interest rate on debt and the return on equity].
ROE and Leverage

3. Suppose the company in Problem 1 has a market-to-book ratio of 1.0. 
   a. Calculate return on equity [ROE], under each of the 3 economic scenarios
      before any debt is issued. Also calculate the %Δ in ROE for economic
      expansion and recession, assuming no taxes.

   Since the firm has a market-to-book value of 1.0, the total equity of the firm is
   equal to the market value of equity. \( \text{ROE} = \frac{\text{NI}}{E} = \frac{\text{NI}}{150,000} \)

   The ROE for each state of the economy under the current capital structure and no
   taxes is:

<table>
<thead>
<tr>
<th>State</th>
<th>Recession</th>
<th>Normal</th>
<th>Expansion</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROE</td>
<td>$\frac{5,600}{150,000}$</td>
<td>$\frac{14,000}{150,000}$</td>
<td>$\frac{18,200}{150,000}$</td>
</tr>
<tr>
<td>ROE</td>
<td>.0373</td>
<td>.0933</td>
<td>.1213</td>
</tr>
</tbody>
</table>

   Sensitivity Analysis: Normal to Recession
   \[ %\Delta \text{ROE} = \frac{(0.0373 - 0.0933)/0.0933 = -0.59985 \text{ or } -60\%} \]

   Sensitivity Analysis: Normal to Expansion
   \[ %\Delta \text{ROE} = \frac{(0.1213 - 0.0933)/0.0933 = 0.3001 \text{ or } 30\%} \]

   b. Repeat part (a) assuming the firm goes through with the recapitalization.
      Assuming no taxes, interest on debt of 5%.
      If the firm goes forward with recapitalization, the new equity value will be:
      Equity = $150,000 - $60,000 or $90,000 [due to reduction of shares outstanding]

      So, the ROE for each state of the economy is: \( \text{ROE} = \frac{\text{NI}}{90,000} \)

      | State       | Recession       | Normal          | Expansion       |
      |-------------|-----------------|-----------------|-----------------|
      | ROE         | $\frac{2,600}{90,000}$ | $\frac{11,000}{90,000}$ | $\frac{15,200}{90,000}$ |
      | ROE         | .0289           | .1222           | .1689           |

   Sensitivity Analysis: Normal to Recession
   \[ %\Delta \text{ROE} = \frac{(0.0289 - 0.1222)/0.1222 = -0.7635 \text{ or } -76.4\%} \]

   Sensitivity Analysis: Normal to Expansion
   \[ %\Delta \text{ROE} = \frac{(0.1689 - 0.1222)/0.1222 = 0.3822 \text{ or } 38.2\%} \]
c. Repeat parts (a) and (b) of this problem considering the fact that the Company has a 35% tax rate.

<table>
<thead>
<tr>
<th></th>
<th>Recession</th>
<th>Normal</th>
<th>Expansion</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBIT</td>
<td>$5,600</td>
<td>$14,000</td>
<td>$18,200</td>
</tr>
<tr>
<td>Less: Interest</td>
<td>$3,000</td>
<td>$3,000</td>
<td>$3,000</td>
</tr>
<tr>
<td>EBT</td>
<td>$2,600</td>
<td>$11,000</td>
<td>$15,200</td>
</tr>
<tr>
<td>Less: Taxes @ 35%</td>
<td>$910</td>
<td>$3,850</td>
<td>$5,320</td>
</tr>
<tr>
<td>NI</td>
<td>$1,690</td>
<td>$7,150</td>
<td>$9,880</td>
</tr>
</tbody>
</table>

ROE

<table>
<thead>
<tr>
<th></th>
<th>Recession</th>
<th>Normal</th>
<th>Expansion</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>.01877</td>
<td>.07944</td>
<td>.10977</td>
</tr>
</tbody>
</table>

Sensitivity Analysis: Normal to Recession
\[
\% \Delta \text{ROE} = \frac{(\.01877 - \cdot07944)/.07944 = -.7637 \text{ or } -76.4\%}
\]

Sensitivity Analysis: Normal to Expansion
\[
\% \Delta \text{ROE} = \frac{(\.10977 - \cdot07944)/.07944 = .3818 \text{ or } 38.2\%}
\]

The \%\Delta ROE is the same as the \% Δ EPS, and also the \%ΔROE remains the same regardless of taxes [i.e., the tax rate has an equal impact on NI for all states of the economy].

12. Calculating WACC
Weston Industries has a debt-equity ratio of 1.5. Its WACC is 12%, and its cost of debt is 12%. The corporate tax rate is 35%.

a. What is Weston’s cost of equity capital.
Compute the weights on the various sources of financing

\[
D/E = 1.5 \Rightarrow D = 1.5E, \text{ so } \frac{D}{D+E} = \frac{1.5E}{1.5E + E} = \frac{1.5}{2.5} = .6 \text{ or } 60\%
\]

\[
\frac{E}{D+E} = 1 - .60 = .4 \text{ or } 40\%
\]

Therefore, \[
\text{WACC} = .6 \times .12 \times (1-.35) + .4 \times k_e
\]

\[
.12 = .0468 + .4 \times k_e
\]

\[
.0732/.4 = k_e
\]

\[
.183 = k_e
\]
12.  

b. What is Weston’s unlevered cost of equity capital?

To find the unlevered cost of equity we use the M&M Proposition 2 with taxes:

\[ k_e = k_{ul} + [k_{ul} - k_D] \frac{D}{E} [1 - t] \]

\[ .183 = k_{ul} + [k_{ul} - .12] \frac{1.5}{1 - .35} \]

\[ .183 = k_{ul} + .975 k_{ul} - .117 \]

\[ .30 = 1.975 k_{ul} \]

\[ .15189 \text{ or } 15.19\% = k_{ul} \]

c. What would the cost of equity be if the debt-to-equity ratio were 2 instead of 1.5 (i.e., more debt relative to equity \( \Rightarrow \) higher leverage)? What if it were 1.0 instead of 1.5 (i.e., more debt relative to equity \( \Rightarrow \) less leverage)?

Using the information and the same methodology as in (b) with the M&M Proposition 2:

With the D/E = 2

\[ k_e = k_{ul} + [k_{ul} - k_D] \frac{D}{E} [1 - t] \]

\[ k_e = k_{ul} + [k_{ul} - .12] \frac{2.0}{1 - .35} \]

\[ k_e = .1519 + [.1519 - .12] [2.0] [1 - .35] = .19337 \text{ or } 19.34\% \]

With the D/E = 1

\[ k_e = k_{ul} + [k_{ul} - k_D] \frac{D}{E} [1 - t] \]

\[ k_e = k_{ul} + [k_{ul} - .12] \frac{1.0}{1 - .35} \]

\[ k_e = .1519 + [.1519 - .12] [1.0] [1 - .35] = .1726 \text{ or } 17.26\% \]

If the D/E = 0 then \[ k_e = k_{ul} = 15.19\% \text{ [i.e., there is no leverage to consider]} \]
18. Firm Value

Old School Corporation expects an EBIT of $9,000 every year forever. Old School currently has no debt, and its cost of equity is 17%. The firm can borrow at 10%. If the corporate tax rate is 35%, what is the value of the firm? What will be the value of Old School if it converts to 50% debt? To 100% debt?

With no debt, we are basically finding the value of the unlevered firm.

\[ V_{UL} = \frac{EBIT \times (1-t)}{k_{ul}} = \frac{$9,000 \times (1-0.35)}{0.17} = \frac{$5,850}{0.17} = $34,411.76 \]

With debt, we simply need to use the equation for the value of a levered firm. With 50% debt, half of the firm’s value is tied up in debt, so the value of the firm is:

\[ V = V_{UL} + \text{Tax rate} \times B \{\text{Debt}\} = $34,411.76 + 0.35 \times \left(\frac{$34,411.76}{2}\right) \]
\[ V = $34,411.76 + $6,022.06 = $40,433.82 \]

With 100% debt, the value of the firm is:

\[ V = $34,411.76 + 0.35($34,411.76) = \left(1.35\right)($34,411.76) = $46,455.88 \]

Note: It is very unlikely anyone would extend 100% debt financing to the firm given the leverage, but if they did, it would be tantamount to owning their owning the company. In addition, the IRS would probably consider the deal more of a purchase and therefore seek to disallow the interest expense deductions on the debt.
21. Cost of Capital

Acetate, Inc. has equity with a market value of $20 million and debt with a market value of $10 million. Treasury bills that mature in one year yield 8% per year, and the expected return on the market portfolio over the next year is 18%. The beta of Acetate’s equity is .90. The firm pays no taxes.

a. What is Acetate’s debt to equity ratio?

\[
\text{Debt/Equity} = \frac{\text{MV}_D}{\text{MV}_E} = \frac{$10\text{ million}}{$20\text{ million}} = .50
\]

b. What is Acetate’s weighted average cost of capital?

First, we need to calculate the cost of equity.

\[
K_e = K_{rf} + \beta (K_M - K_{rf}) = .08 + .90 (.18 - .08) = .17 \text{ or } 17\%
\]

We need to remember that one of the MM assumptions is that the firm’s debt is risk-free, so we can use the Treasury bill rate as the cost of debt for the company. In the absence of taxes, a firm’s weighted average cost of capital is equal to:

\[
R_{WAAC} = \left[\frac{D}{D+E}\right]K_D + \left[\frac{E}{D+E}\right]K_e
\]

\[
R_{WAAC} = \left[\frac{$10\text{ million}}{$30\text{ million}}\right](.08) + \left[\frac{$20\text{ million}}{$30\text{ million}}\right](.17)
\]

\[
R_{WAAC} = .14 \text{ or } 14\%
\]

So, the WAAC is a blended rate based on the relative proportion of debt to equity financing, ignoring tax effects.

c. What is the cost of capital for an otherwise identical all-equity firm?

According to MM Proposition 2 with no taxes:

\[
R_E = R_{UL} + \left[\frac{D}{E}\right] \left[R_{UL} - R_D\right]
\]

\[
.17 = R_{UL} + [.5] \left[R_{UL} - .08\right] \Rightarrow R_{UL} = .14 \text{ or } 14\%
\]

This result is consistent with MM’s proposition that, in the absence of taxes, the cost of capital for an all-equity firm is equal to the weighted average cost of capital for an otherwise identical levered firm.
22. Homeade Leverage

The Veblen Company and the Knight Company are identical in every respect except that Veblen is not levered. The market value of Knight Company’s 6% bonds is $1 million. Financial information for the two firms appears here. All earnings streams are perpetuities. Neither firm pays taxes. Both firms distribute all earnings available to common stockholders immediately.

<table>
<thead>
<tr>
<th></th>
<th>Veblen</th>
<th>Knight</th>
</tr>
</thead>
<tbody>
<tr>
<td>Projected operating income</td>
<td>$300,000</td>
<td>$300,000</td>
</tr>
<tr>
<td>Year-end Interest on Debt</td>
<td>----------</td>
<td>$60,000</td>
</tr>
<tr>
<td>Market Value of Stock</td>
<td>$2,400,000</td>
<td>$1,714,000</td>
</tr>
<tr>
<td>Market Value of Debt</td>
<td>----------</td>
<td>$1,000,000</td>
</tr>
</tbody>
</table>

a. An investor who can borrow at 6% a year wishes to purchase 5% of Knight’s equity. Can he increase his dollar return by purchasing 5% of Veblen’s equity if he borrow so that the initial net costs of the two strategies are the same?

To purchase 5% of Knight’s equity, the investor would need:

Knight investment = .05($1,714,000) = $85,700

To purchase 5% of Veblen [debt free], the investor would need:
Veblen Investment = .05($2,400,000) = $120,000

In order to compare dollar returns, the initial net cost of both positions should be the same. Therefore, the investor will need to borrow the difference between the two amounts or:

Amount of borrowings = $120,000 - $85,700 = $34,300

An investor who owns 5% of Knight’s equity will be entitled to 5% of the firm’s earnings available to common stockholders at the end of each year. While Knight’s expected operating income is $300,000, it must pay $60,000 in interest to debt holders before any distribution from earnings to shareholders. So, the amount available to the equity purchaser dividends would be:

Cash flow from Knight to Purchaser = .05($300,000 - $60,000) = $12,000

Veblen will distribute all of its earnings to shareholders, so

Cash flow from Veblen to Purchaser = .05($300,000) = $15,000
However, to have the same initial cost, the purchaser has borrowed $34,300 to invest in Veblen so interest has to be paid on the borrowings.

Net cash flow to purchaser on Veblen stock will be:

$15,000 - .06($34,300) = $12,942

For the same initial cost, the investment in Veblen produces a higher dollar return.

b. Given the two investment strategies in (a), which will investors choose? When will this process cease [theoretically]?

Both of the two strategies have the same initial cost. Since the dollar return to the investment in Veblen is higher, investors will choose to invest in Veblen up to the point where the rising price of Veblen stock causes the market value of Veblen’s equity to rise to the point where the two deals are exactly the same [i.e., the advantages will be arbitraged away]. Another factor to be considered is the 6% financing cost which could change and alter the relative differences in the two alternatives [i.e., if the financing rate were 8% rather than 6%, the net cash flow from the Veblen purchase would be: $15,000 - $2,744 = $12,256 making the deal slightly less attractive].
